## Abstract

Ultrasonic-based SHM (Structural Health Monitoring) applications commonly rely on the use of piezo-electric patches to emit and receive ultrasonic waves. The objective is to study the propagation of the waves through a structure to assess its structural integrity. Because of the elevated number of echoes and possible modes of propagation of the waves within the structure, those applications suffer from a burden of signal processing. This paper presents a composite piezo-electric patch that was designed and successfully tested for reducing the complexity of the SHM detection schemes by selecting the mode and direction of the Lamb waves received. The piezo-composite is composed of a row of eight independent ceramic pillars separated with polymer, so it is a 1-D matrix of independent piezo-patches. Used with adequate electronics and signal processing, it was shown that it allowed selecting the direction and the mode of the Lamb waves.

## 1 Introduction

### 1.1 Problematic

SHM requires the fusion of different engineering disciplines such as signal processing, electronics, acoustics, or mechanics. One of the most common detection techniques is to emit and receive ultrasonic waves with piezo-electric transducers attached to the structure. A simple setup to assess the propagation of the wave is to have two piezo-patches, one acting as emitter and the other acting as a receiver. The properties of the wave transmitted from the emitter to the receiver will be very likely to change in the case of a defect between the two patches.

These SHM detection schemes suffer from a burden of signal processing due to different modes of propagation and the large number of interfering echoes [1]. Mode and direction selectivity of the waves is a way to reduce the complexity of the signal processing, by selecting one mode of propagation, and by looking only into the transmitted waves and not their echoes.

For acoustic waves at frequencies around several hundred kHz, it can be considered that only the  $S_0$  mode and  $A_0$  mode are present [2]. The  $S_0$  mode is known as the symmetric mode, the  $A_0$  mode is the anti-symmetric mode. An interesting property is that the  $S_0$  mode is faster than the  $A_0$  mode, i.e. the  $S_0$  mode is always the first to arrive to the receiver. The  $S_0$  mode is more affected by the defects than the  $A_0$  mode, thus there is a strong interest in this mode for SHM detection schemes.

### 1.2 Concept

The piezo-composite structure is a way to obtain mode and direction selectivity as it features several independent patches separated with a fixed pitch ([2], [3]), as shown on **Figure 1.1**.

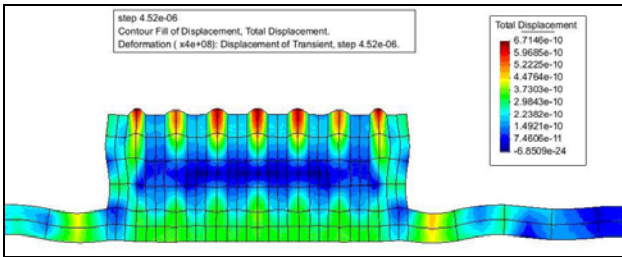

**Figure 1.1** Schematic view of a piezo-composite patch featuring 8 elements.

The selective reception technique is based on the knowledge that the modes propagate at different speeds. The piezo-composite receives several signals from different positions on the structure. By simple processing of those signals, it is possible to distinguish waves propagating at different velocities. This is done by summing the different signals received with a delay corresponding to the time of propagation of the selected wave from one element to the next.

### 1.3 Modelling

A FEM model of the piezo-composite was built and simulated with the ATILA software [4]. The piezo-composite

targeted features 8 channels, and has a mechanical resonance frequency at 500 kHz. This FEM model is shown on **Figure 1.2**.

**Figure 1.2** FEM model of the piezo-composite patch.

With this FEM model, transient simulations of the selective reception technique were performed. It was shown that this technique was theoretically able to amplify the waves for the mode and direction selected.

## 2 Design of the piezo-composite patch

With encouraging results obtained in simulation, the objective was to obtain a proof of concept with practical tests. A piezo-composite patch was manufactured based on the model.

### 2.1 Manufacturing process

The most part of the manufacturing of the piezo-composite patch was done by Ferroperm Piezoceramics which has experience in piezo-patches [5]. The manufacturing process was developed in close cooperation between Cedrat Technologies and Ferroperm Piezoceramics. The different steps of the manufacturing process are schematically represented on **Figure 2.1**.

**Figure 2.1** Schematic representation of the manufacturing process of the piezo-composite patches.

The potting of the polymer was done by Cedrat Technologies and the rest of the manufacturing was done by Ferroperm Piezoceramics.

The polymer used was an electrically insulating silicon-based polymer, with low viscosity. The resulting samples of piezo-composite are shown on **Figure 2.2**:

**Figure 2.2** Piezo-composite samples used for the tests.

On the different samples, the resonance frequency is measured around 530 kHz, which is not far from the simulation which predicted 500 kHz. The capacitance of the single elements of the piezo-composite is approximately 60pF. The characteristics of the piezo-composite patches are compared, and it is found that there is a low repeatability between their frequency responses.

### 2.2 Integration

The samples of the first version of the piezo-composite were integrated on aluminium test plates, where their functionality could be assessed. Two piezo-composite patches are placed on a plate, so that the transmission of the waves from one patch to the other can be studied. The piezo-composite patches are first bonded on the alloy plate. The wire connections for the ground and single elements are then soldered on the electrodes. The **Figure 2.3** is a picture of a piezo-composite patch after mounting on the alloy test plate.

**Figure 2.3** Picture of an alloy test plate with an integrated piezo-composite.

After integration on the alloy test plates, the piezo-composite patches are characterized again. It is found that the resonance frequency has increased to 600 kHz. This increase is attributed to the parasitic stiffness of the bonding and alloy plate.

### 3 Electronics

For the purpose of driving and sensing the signals on piezo-patches, a specific electronic board was designed. This board, named LWDS45-2 [6], is shown on **Figure 3.1**.

**Figure 3.1** Picture of the LWDS45-2, multi-channels drive and sense electronic for piezo-patches.

The LWDS45-2 electronics are designed to be versatile in order to fulfil the specific needs of the SHM domain. A LWDS45-2 features 4 independent channels. Each channel of the LWDS45-2 features a power amplifier that can drive piezo-electric patches up to 10nF at 30Vpp, with a bandwidth up to 2 MHz depending on the load. There is a low-noise conditioning unit with selectable gain to monitor the signals received on the patches. The LWDS45-2 offers the unique functionality, called PULSECHO, of being able to switch a patch from excitation to reception mode (and reciprocally) in less than 1 $\mu$ s. This allows to send a signal with a patch, and to monitor the echo of the signal on the exact same patch. This functionality is controlled through a logic input. The structure of a channel of the LWDS45-2 is presented on **Figure 3.2**.

**Figure 3.2** Structure of a channel of the LWDS45-2.

The LWDS45-2 offers modularity, several LWDS45-2 can be plugged in a rack to obtain more channels if desired.

There is also the possibility of integrated solutions, as the LWDS45-2 features a daughter board that can be used as embedded board, as shown on **Figure 3.3**.

**Figure 3.3** 4-channels PULSECHO amplifier. Daughter board or embedded board.

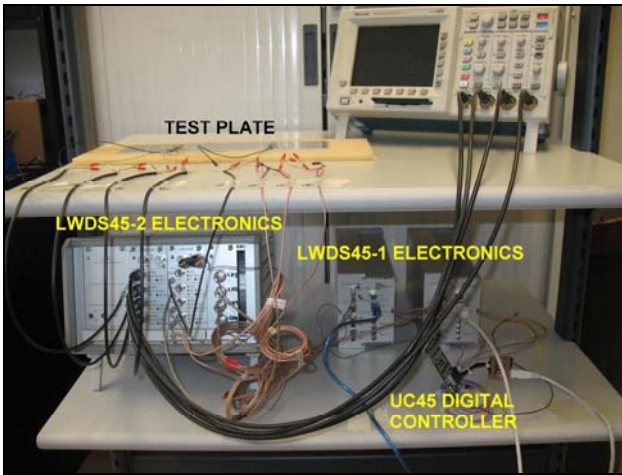

With this multi-channel architecture, the LWDS45-2 is ideally suited for applications using piezo-composite arrays.

### 4 Practical tests

After the integration of the patches on the test plates, tests are run on the plates to verify that the mode and direction selectivity of the Lamb waves can be applied in practice.

#### 4.1 Test setup

The LWDS45-2 electronics are used for the emission and reception of the waves on the piezo-elements. One piezo-composite is used for the emission of the acoustic wave. It has all its elements connected together so that it reduces to the case of a bulk patch. The excitation signal is a sine burst at 600 kHz windowed by a Hanning function generated. This signal is generated with LWDS45-1 electronics [1], and fed to the LWDS45-2 for driving the piezo-composite. The second piezo-composite is used in reception. The consecutive elements of the piezo-composite are paired two by two so that only 4 channels are sufficient to sample the signals received. A 4-channel oscilloscope is used to sample the signals received. The test setup is presented on **Figure 4.1**.

**Figure 4.1** Photo of the test setup.

After sampling of the received signals with the scope, they are extracted to be processed offline. The distance between elements is fixed by the construction of the piezo-composite. The speed of propagation of the  $A_0$  and  $S_0$  modes can be computed knowing the material and thickness of the plate. Thus, the delay to apply for the mode selection can be easily computed as  $T_{delay} = Pitch / Speed$ .

## 4.2 Test results

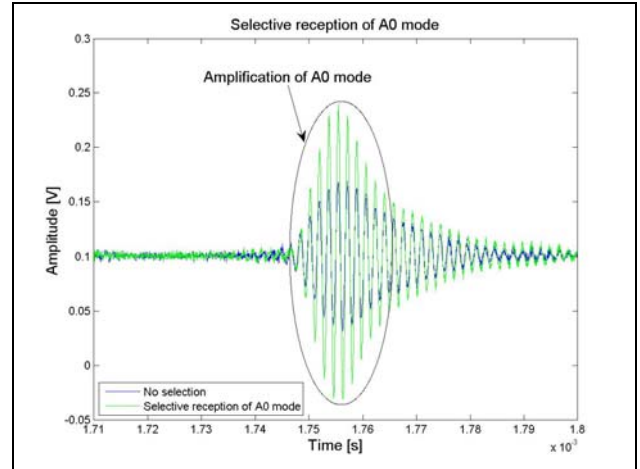

The test is run for selecting the  $S_0$  mode. The signals received are used to reconstruct the interesting signal with the selective reception technique. The signal reconstructed with proper delay is compared with the signal reconstructed without delay, which is equivalent to the case of a bulk patch. The result of this comparison is shown on **Figure 4.2**.

**Figure 4.2** Performance of the selective reception technique with the  $S_0$  mode.

As can be seen on the previous figure, the selective reception technique improves significantly the quality of the signal due to the  $S_0$  mode. The  $S_0$  mode is drowned in the noise, but appears when the selective reception technique is applied.

The same test can be run for the selection of the  $A_0$  mode, and the results are similar. The application of the selective reception technique to the  $A_0$  mode allows amplifying it, as it can be seen on the **Figure 4.3**.

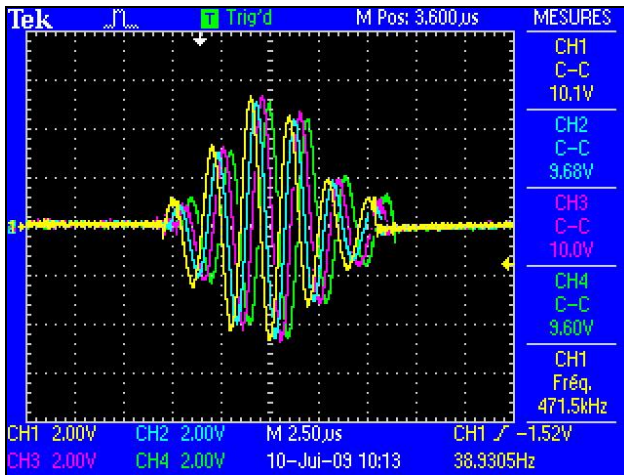

**Figure 4.3** Performance of the selective reception technique with the  $A_0$  mode.

## 5 Piezo-composite patch as a transducer

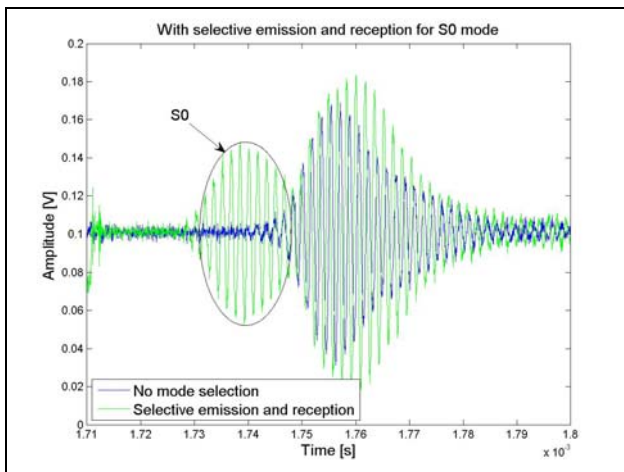

It has been shown that the piezo-composite patch can be used as a smart sensor to select the acoustic waves at reception. Work has also been carried out to use the patch as a smart actuator, to select the mode and direction of propagation at emission. A technique similar to that of the selective reception can be applied at emission to choose the mode and direction of propagation.

The principle is to generate the same signal on the different elements of the piezo-composite, but with a particular delay. This delay corresponds to the time of propagation of the wave at desired speed from one element to the next, i.e. the same delay as for selective reception. A LWDS45-2 is used for the emission, with four independent channels at emission, each driving a pair of elements. The delay is set with a UC45 digital controller that triggers the channels of the LWDS45-1 to generate the appropriate signals. The **Figure 5.1** shows an example of the signals generated on the piezo-composite to achieve selective emission.

**Figure 5.1** Four excitation signals to obtain selective emission.

Tests are run with the emitting patch using the selective emission technique to select the  $S_0$  mode, in the direction of the receiving patch. The receiving patch uses the selective reception technique for the  $S_0$  mode coming from the emitting patch. By combining the two techniques simultaneously, the mode and direction selection is significantly improved, as shown on **Figure 5.2**.

**Figure 5.2** Performance of the mode and direction selection techniques with  $S_0$  mode.

The use of the two selective techniques took the  $S_0$  mode out of the noise so that it can easily be detected. Its properties can be studied to detect the presence of a defect on the surface of transmission, i.e. between the patches.

It is also possible to use the combination of the two techniques for selecting the  $A_0$  mode, as it can be seen on the **Figure 5.3**.

**Figure 5.3** Performance of the mode and direction selection techniques with  $A_0$  mode.

## 6 Conclusion

A piezo-composite patch featuring 8 independent elements was simulated, designed, and finally tested in practice. The concept of a piezo-composite patch to select the mode and direction of propagation of acoustic waves was applied. It was shown that the selective techniques allow to amplify significantly the chosen mode in the direction considered.

The next step for the development of this technology is to assess the robustness of the piezo-composite versus environmental conditions such as those found in aeronautics.

## 7 Acknowledgements

The research leading to these results has been carried out in the frame of the AISHA II project, which has received funding from the European Community's Seventh Framework Programme [FP7/2007-2013] under grant agreement n°212912.
